

Not Finished, But Abandoned

by

Cameron T. Kuchta

A dissertation submitted in partial fulfillment of
the requirements for the degree of

Doctor of Philosophy

(Physics)

at the

UNIVERSITY OF WISCONSIN–MADISON

2026

Date of final oral examination: 01/01/2100

The dissertation is approved by the following members of the Final Oral Committee:

Jane Doeverything, Professor, Electrical Engineering

John Dosomethings, Associate Professor, Electrical Engineering

ACKNOWLEDGMENTS

It is customary for authors of academic books to include in their prefaces statements such as this: "I am indebted to ... for their invaluable help; however, any errors which remain are my sole responsibility." Occasionally an author will go further. Rather than say that if there are any mistakes then he is responsible for them, he will say that there will inevitably be some mistakes and he is responsible for them....

Although the shouldering of all responsibility is usually a social ritual, the admission that errors exist is not — it is often a sincere avowal of belief. But this appears to present a living and everyday example of a situation which philosophers have commonly dismissed as absurd; that it is sometimes rational to hold logically incompatible beliefs.

— DAVID C. MAKINSON (1965)

Above is the famous "preface paradox," which illustrates how to use the `wbepi` environment for epigraphs at the beginning of chapters. You probably also want to thank the Academy.

Abstractxxiii

1 Introduction 1

1.1 *What the heck is a plasma* 1

1.1.1 Plasmas in the universe 1

1.1.2 How do plasmas affect us on earth? 1

1.1.3 Where does magnetic reconnection play into this whole shabang? 1

1.2 *Magnetic Reconnection* 1

1.2.1 The Generalized Ohm's Law 1

1.2.1.1 How do we derive this? 1

1.2.1.2 A breakdown of the terms 1

1.2.2 Regimes of Reconnection 1

1.2.2.1 Reconnection scaling parameters 1

1.2.2.2 Where do various systems line up? 2

1.2.2.3 What are we interested in? 2

1.2.3 Sweet-Parker Reconnection 2

1.2.3.1 A quick historical detour 2

1.2.3.2 What are the assumptions that go into Sweet-Parker? 2

1.2.3.3 Sweet-Parker Reconnection Rate Derivation 2

1.2.3.4 Application to Real Systems 2

1.2.3.4.1	What are some example parameters where reconnection occurs? .	2
1.2.3.4.2	What time scales does Sweet-Parker predict?	2
1.2.3.4.3	What did we miss?	2
1.2.4	Hall Reconnection	2
1.2.4.1	Why should the Hall term appear?	2
1.2.4.1.1	What is the relevant physics that sets when the hall term matters .	2
1.2.4.1.2	In what kind of plasmas does the hall term appear and when does it not?	2
1.2.4.2	What does hall reconnection look like . . .	3
1.2.4.3	What's missing?	3
1.2.5	Kinetic Reconnection	3
1.2.5.1	What makes kinetic reconnection "kinetic"? .	3
1.2.5.1.1	What do collisions do?	3
1.2.5.1.2	What makes a system kinetic? . .	3
1.2.5.2	Where does Pressure Anisotropy come from? .	3
1.2.5.2.1	Movement of flux tube	3
1.2.5.2.2	Effect of background field	3
1.2.5.3	How does pressure anisotropy change what the reconnection looks like	4
1.2.5.3.1	Thinner reconnection layer?	4
1.2.5.3.2	Marginal Firehose Condition . . .	4
1.2.5.3.3	Concluding: what features should we look for in the data?	4
1.2.5.4	Why do we want to measure it?	4
1.2.5.4.1	Simulation result overview	4
1.2.5.4.2	Spacecraft result overview	4

1.2.5.4.3	Experimental result?	4
1.3	<i>Experimental Setup</i> 5	
1.3.1	Overall how does our experiment progress	5
1.3.2	Initial field	6
1.3.2.1	Helmholtz	6
1.3.2.2	Permanent magnets	6
1.3.2.3	Toroidal	6
1.3.2.3.1	Shifted coil	6
1.3.2.3.2	Axial coil	6
1.3.2.4	Perturbation coils	6
1.3.3	Plasma Generation	6
1.3.3.1	How do our guns work	6
1.3.3.1.1	Gas lines	6
1.3.3.1.2	PFNs	6
1.3.3.1.3	Puff trigger	6
1.3.3.1.4	How to breakdown	6
1.3.3.2	How are the guns placed for injection? . .	6
1.3.3.2.1	How much do they fill the machine	6
1.3.3.2.2	What sets the filling fraction . . .	6
1.3.3.3	What goes wrong with them	7
1.3.3.3.1	Burning up	7
1.3.3.3.2	Burn holes in wall because of back- ground field	7
1.3.3.3.3	Air cooling	7
1.3.3.3.4	Optimizing gun operation	7
1.3.4	Drive field	7
1.3.4.1	Individual coils	7
1.3.4.1.1	Zone's between coils as plasma sources	7
1.3.4.2	Drive Cylinder	7
1.3.5	Diagnostics Overview	7

1.3.5.1	Bdot probes	7
1.3.5.1.1	Basic principles	7
1.3.5.1.2	Probe types	7
1.3.5.1.3	Data Interpretation	8
1.3.5.2	Hall probes	8
1.3.5.2.1	Basic principles	8
1.3.5.2.2	Issues and feasibility	8
1.3.5.3	Langmuir probes	8
1.3.5.3.1	Basic principles	8
1.3.5.3.2	What do we need to do to make them work for our device?	8
1.3.5.3.3	Look into XXX chapter	8
1.3.5.4	Fast camera	8
1.3.5.4.1	What can we see with it?	8
1.3.5.4.2	Potential use cases	8
1.3.6	How does the experiment compare to space	9
1.3.6.1	Simulation benefits and results	9
1.3.6.2	Space benefits and results	9
1.3.6.3	Lab benefits and results	9
1.3.7	Other lab reconnection experiments	9
1.3.7.1	VTF, MRX, FLARE	9
1.3.7.2	Exploding wire arrays	9
1.3.7.3	Laser based	9

2 Pressure Wave 10

2.1 Introduction 10

2.2 Observations that lead us to look at this wave 11

2.2.1	Speed probe measurements	11
2.2.1.1	Flux expansion before shock layer	11
2.2.1.2	Wavefront that depends on configuration	11
2.2.2	Simulations	11

2.2.2.1	Different n and drive change feature	11
2.2.2.2	Change reconnection layer post reflection .	11
2.3	<i>Physical understanding of wave</i>	11
2.3.1	Initial plasma configuration	11
2.3.2	Release in magnetic pressure	11
2.3.2.1	What would happen if plasma was immo- bile (replaced with perfect conductor) . .	11
2.3.3	Wavefront tells plasma about pressure Release . . .	11
2.3.3.1	Analogous system	11
2.3.4	Modeling magnetic field response	12
2.3.4.1	How do we create this model	12
2.3.4.2	Pressure wave is like a shield	12
2.3.4.3	Example	12
2.3.4.4	Why have we mentioned this?	12
2.3.4.4.1	Important for probe calibrations .	12
2.3.4.4.2	Good for predicting effects of dif- ferent coil configurations	12
2.4	<i>Wave Simulation</i>	12
2.4.1	Approximations	12
2.4.2	Linearizing MHD	12
2.4.3	Plasma Equilibrium + Symmetries	12
2.4.3.1	Types of Equilibrium	12
2.4.3.1.1	theta-pinch	12
2.4.3.1.2	screw-pinch	12
2.4.3.2	Types of Symmetries	12
2.4.3.2.1	z-symmetry	12
2.4.3.2.2	toroidal-symmetry	12
2.4.4	Simplified 1D equation	13
2.4.4.1	What does this look like?	13
2.4.4.2	Normalizations	13

2.4.4.3	Normalized equation	13
2.4.5	Boundary conditions	13
2.4.5.1	$r = 0$ Boundary	13
2.4.5.1.1	$v = 0$ option	13
2.4.5.1.2	$\xi = 0$ option	13
2.4.5.1.3	What do we choose?	13
2.4.5.2	$r = R$ Boundary	13
2.4.5.2.1	What is physically happening at high radius in the coils?	13
2.4.5.2.2	Loop voltage sets dB_z/dt	13
2.4.5.2.3	Assuming MHD so far so let's keep assuming!	13
2.4.5.2.4	Vloop signal shape	13
2.4.6	Initial conditions	14
2.4.6.1	What form can we expect plasma to take? .	14
2.4.6.2	What form do we use for these results . . .	14
2.4.7	What does our simulation show?	14
2.4.7.1	There is a wavefront traveling inwards at fast magnetosonic	14
2.4.7.1.1	Low beta approximation giving Alfven	14
2.4.7.2	Once wavefront passes, plasma moves out	14
2.4.7.3	Converting to B_{dot}	14
2.4.7.4	In B_{dot} we see flux moving outwards . . .	14
2.5	<i>How do we apply it to real data?</i>	14
2.5.1	Base requirements	14
2.5.1.1	Cylindrical symmetry	14
2.5.1.2	Releasing magnetic pressure at high radius	14
2.5.1.3	Measurements along a radial chord	14
2.5.1.4	Known initial field	14

2.5.2	Extracting the wave speed from the data	14
2.5.2.1	Wave tracking	14
2.5.2.1.1	Edge finding	14
2.5.2.1.2	Inertia	15
2.5.2.1.3	Monte-carlo	15
2.5.2.1.4	Centered finite difference	15
2.5.2.1.5	Mean + Standard Deviation of Speed	15
2.5.3	Getting the density	15
2.5.3.1	Using the alfven speed	15
2.5.4	Minimum measurable density	15
2.5.4.1	Assuming sample resolution	15
2.5.4.1.1	What does this assumption derive	15
2.5.4.1.2	How does it compare to the data .	15
2.5.4.1.3	We need a better approximation .	15
2.5.4.2	Assuming sub-sample resolution	16
2.5.4.3	A more complex model assuming the plasma is a step function * linear	16
2.6	<i>Does it reproduce langmuir probe results</i>	16
2.6.1	Experimental setup	16
2.6.1.1	Drive cylinder	16
2.6.1.2	Te probe along equator	16
2.6.2	Results	16
2.6.2.1	Langmuir probe minimum measurable den- sity	16
2.6.2.2	Impacts of simple Langmuir model vs BRL	16
2.6.2.3	What happens to the wave shape in simu- lation vs. experiment	16
2.6.2.3.1	Two-fluid dispersion	16
2.6.2.3.2	How might we expect this to change the wave	16

2.6.2.3.3	How to simulate evolution approximately	17
2.6.2.3.4	Dispersion simulation results . . .	17
2.7	<i>Applications</i>	17
2.7.1	Other machines where this is applicable	17
2.7.2	Diagnosing gun failures	18
2.7.3	Measuring effect of different gun number and Helmholtz strength	18
2.7.3.1	Gun number	18
2.7.3.2	Helmholtz	18
2.7.4	Measuring diffusion coefficient	18
2.7.4.1	Diffusion theoretical model	18
2.7.4.2	Diffusion simulations	18
2.7.4.3	Applications of pressure wave model . . .	18
2.8	<i>Future Research</i>	19
2.8.1	Better wave tracking	19
2.8.1.1	Cross-correlation	19
2.8.1.2	Dynamic Time Warping	19
2.8.1.3	Using a model of what the wave looks like	19
2.8.2	Using fast-magnetosonic speed instead of alfvén . .	19
2.8.2.1	Will this iteratively converge?	19
3	Multi-tip Langmuir Probe	20
3.1	<i>What's a Langmuir probe</i>	20
3.1.1	Basic Construction	20
3.1.2	Extracting Plasma Parameters	21
3.1.3	Plasma Perturbation	21
3.1.3.1	Unmagnetized Perturbation	21
3.1.3.2	Magnetic Field Effects	22
3.1.3.3	Perturbations in our System	22
3.1.3.3.1	Geometric Considerations	22

3.1.3.3.2	Magnetic Field Considerations . .	23
3.2	<i>Hardware</i>	23
3.2.1	Physical Constraints	23
3.2.2	Shaft Components	24
3.2.2.1	Garages	24
3.2.2.2	Shaft materials	25
3.2.2.3	Centering Collet	25
3.2.2.4	Feed-thru	26
3.2.3	Tip Components	26
3.2.3.1	Probe body	26
3.2.3.2	Tip material + size	27
3.2.3.2.1	Why use Mo	28
3.2.3.2.2	Size considerations	28
3.2.3.3	Tip Shielding	28
3.2.3.3.1	Why shield at all?	28
3.2.3.3.2	First order mach effects to avoid .	29
3.2.4	B-dot Coils	29
3.2.4.1	How many wraps	30
3.2.4.2	Approximate area	30
3.2.5	Length Scales	30
3.3	<i>Circuitry</i>	30
3.3.1	Bias Source	30
3.3.1.1	Manually Controlled	30
3.3.1.1.1	Principles of operation	30
3.3.1.1.2	Problems	30
3.3.1.2	Remote Controlled	30
3.3.1.2.1	Principles of operation	30
3.3.1.2.2	Problems	30
3.3.1.2.3	Calibration	30
3.3.2	Probe Circuit	31

3.3.2.1	Principles of operation	31
3.3.2.1.1	Plasma draws current	31
3.3.2.1.2	Voltage drop across sense resistor	31
3.3.2.1.3	Measure high frequency voltage drop	31
3.3.2.2	Single-ended measurement	31
3.3.2.3	Differential measurement	31
3.3.2.4	Circuit Solution	31
3.3.2.4.1	How do we solve this	31
3.3.2.4.2	equations	31
3.3.2.4.3	Assumptions	32
3.3.2.5	Calibration	32
3.3.2.5.1	Calibrating in isat	32
3.3.2.5.2	Calibrating on the exponential . .	32
3.3.2.5.3	Bayesian calibration	32
3.3.2.5.4	Calibration using pressure wave .	32
3.3.3	Bdot coils	32
3.3.3.1	In-shaft circuit	32
3.3.3.1.1	Why do we have that?	32
3.3.3.1.2	Where is it placed approximately?	32
3.3.3.2	Circuit model	32
3.3.3.3	Calibration	32
3.3.3.3.1	Directional	32
3.3.3.3.2	Transfer Function	32
3.4	<i>Plasma Theory</i> 33	
3.4.1	Simple Plasma Theory (Hutchinson)	33
3.4.1.1	Derivation	33
3.4.1.2	Pros & Cons	33
3.4.2	BRL	33
3.4.2.1	Idea behind it	33

3.4.2.2	Approximations of it	33
3.4.2.2.1	Planar probe	33
3.4.2.2.2	Chen Approximation	33
3.4.2.2.3	Even more approximation	33
3.4.3	Effect of electric fields	33
3.4.3.1	Where does the electric field come from . .	33
3.4.3.1.1	Majority inductive	33
3.4.3.1.2	Some static	33
3.4.3.2	What does it do to the tip measurements .	33
3.4.3.2.1	Theoretical understanding	33
3.4.3.2.2	Physical reality	34
3.4.4	Minimum measurable density	34
3.4.4.1	What's the debye Length	34
3.4.4.2	Sheath scale	34
3.4.4.3	Tip-tip sheath overlap	34
3.5	<i>Curve Fitting</i> 34	
3.5.1	Least squares Fitting	34
3.5.1.1	Benefits (easy)	34
3.5.1.2	Issues (not representative of error)	34
3.5.2	ODR	34
3.5.2.1	What does error look like in our signals . .	34
3.5.2.2	How does ODR take that into account . . .	34
3.5.2.3	How to apply parameter bounds	34
3.5.2.3.1	Our method	34
3.5.2.3.2	Other options	34
3.5.3	Monte-carlo Fitting	35
3.5.3.1	What kind of fits do we get if we just trust a local minimum	35
3.5.3.2	How do we sample initial conditions . . .	35

3.5.3.3	More robust methods for getting global minimums	35
3.5.4	Combining multiple shots	35
3.5.4.1	Using some time points from each shot . .	35
3.5.4.2	Combining all IV points and fitting that . .	35
3.5.4.3	Problems	35
3.5.4.3.1	Timing alignment	35
3.5.4.3.2	Variability of plasma parameters .	35
3.6	<i>Results</i> 35	
3.6.1	Measurement of low densities	36
3.6.1.1	How does Hutchinson vs BRL treat ion sat- uration	36
3.6.1.2	What are the experimental predictions that Hutchinson vs BRL have	36
3.6.1.3	How does that change the results	36
3.6.2	Noise resilience	36
3.6.3	Fits more accurate	36
3.6.4	Extracting electric fields	36
3.6.4.1	Where do we expect electric fields to be . .	36
3.6.4.2	Do we see them there	36
4	Pressure Anisotropy Probe 37	
4.1	<i>How can we measure Pressure Anisotropy</i> 37	
4.1.1	Thomson Scattering	37
4.1.1.1	Pros	37
4.1.1.2	Cons	37
4.1.2	Directional Langmuir Probe	37
4.1.2.1	Pros	37
4.1.2.2	Cons	37
4.2	<i>Hardware</i> 38	
4.2.1	Shaft Components	38

4.2.1.1	Garages	38
4.2.1.2	Shaft materials	38
4.2.1.3	Centering Collet	38
4.2.1.4	Feed-thru	38
4.2.2	Tip Components	38
4.2.2.1	Probe body	38
4.2.2.1.1	3D printed	38
4.2.2.1.2	Both sides fit together	38
4.2.2.2	Tip material + size	38
4.2.2.2.1	Shell material	38
4.2.2.2.2	Core material	38
4.2.2.3	Tip Shielding	39
4.2.2.3.1	Shell Shielding	39
4.2.2.3.2	Core Shielding	39
4.2.3	Bdot Coils	39
4.2.4	Connecting Bdot - Probe - Shaft	39
4.2.5	Length Scales	39
4.3	<i>Circuitry</i> 39	
4.3.1	Bias Source	39
4.3.1.1	Principles of operation	39
4.3.1.1.1	Charging	39
4.3.1.1.2	Discharging	39
4.3.1.1.3	Swapping polarity	39
4.3.1.2	How do we do this	39
4.3.1.2.1	Cannibalization	39
4.3.1.2.2	Discharging	40
4.3.1.2.3	Safety	40
4.3.1.2.4	Cap arcing	40
4.3.1.2.5	Reducing voltage drop due to in- ductance	40

4.3.1.2.6	Reversing polarity	40
4.3.1.2.7	LabView (ew)	40
4.3.1.3	Calibration	41
4.3.1.3.1	Calibrating power supply output	41
4.3.1.3.2	Calibrating cap bank output . . .	41
4.3.2	Probe Circuit	41
4.3.2.1	Single-ended measurement	41
4.3.2.1.1	TREX cells	41
4.3.2.1.2	Why was this bad	41
4.3.2.1.3	How long did we spend on this :(	41
4.3.2.2	Differential measurement	41
4.3.2.2.1	Parallel circuitry	41
4.3.2.3	Figuring out grounds	41
4.3.2.3.1	Types of grounds on the ACQ . .	41
4.3.2.3.2	Routing grounds	41
4.3.2.4	Swapping current paths	42
4.3.2.4.1	Why do we want to do this	42
4.3.2.4.2	Circuitry to do this	42
4.3.2.4.3	How does this change results . . .	42
4.3.2.5	Circuit Solution	42
4.3.2.5.1	Solution	42
4.3.2.5.2	Assumptions	42
4.3.2.6	Calibration	42
4.3.2.6.1	Calibrating in isat	42
4.3.2.6.2	Calibrating on the exponential . .	43
4.3.2.6.3	Rotation calibration	43
4.3.2.7	The path to ground	43
4.3.2.7.1	Why do we have to care	43
4.3.2.7.2	How do we set it	43
4.3.2.8	Capacitive coupling	43

4.3.2.8.1	Where does it come from	43
4.3.2.8.2	Where do we see it	43
4.3.2.8.3	Magnitude of effect	43
4.3.2.8.4	Removing effect	43
4.4	<i>Plasma Theory</i> 44	
4.4.1	A full model	44
4.4.1.1	Plasma Distribution	44
4.4.1.2	Ion particle flux	44
4.4.1.2.1	Mach effects	44
4.4.1.3	Electron particle flux	44
4.4.1.3.1	Minimum velocity	44
4.4.1.3.2	Area	44
4.4.1.3.3	Particle Flux	44
4.4.1.4	Theoretical JV curves	44
4.4.1.4.1	Reading radar plots	44
4.4.2	Individual tip fitting	44
4.4.2.1	Why do this instead	44
4.4.2.2	Methods	44
4.4.2.2.1	Aforementioned methods	44
4.4.2.2.2	Exponential	45
4.4.2.3	Extracting plasma parameters	45
4.4.2.3.1	Spherical harmonics	45
4.4.2.3.2	Error bars	45
4.5	<i>Curve Fitting</i> 45	
4.5.1	Combining multiple shots	46
4.5.1.1	Timing alignment	46
4.5.1.1.1	$B_z = 0$ alignment	46
4.5.1.1.2	B_{dot} cross correlation	46
4.5.1.1.3	Result comparison	46
4.5.1.2	Averaging of core data	46

4.5.1.2.1	Weighted average of relay on/off .	46
4.5.2	Fitting shell	47
4.5.2.1	Use all shell data	47
4.5.2.2	Fit using BRL	47
4.5.2.3	Fits pretty good	47
4.5.3	Fitting core	47
4.5.3.1	Fitting using full routine	47
4.5.3.1.1	Slow	47
4.5.3.1.2	Model not perfectly representative	47
4.5.3.2	Fitting tips independently	47
4.5.3.2.1	Individual fitting method	47
4.5.3.2.2	Holding Vprobe constant	47
4.5.3.2.3	Exponential fitting method	47
4.5.3.2.4	Spherical harmonics	47

ABSTRACT

FIXME: basically a placeholder; do not believe

I did some research, read a bunch of papers, published a couple myself, (pick one):

1. ran some experiments and made some graphs,
2. proved some theorems

and now I have a job. I've assembled this document in the last couple of months so you will let me leave. Thanks!

1 INTRODUCTION

1.1 What the heck is a plasma

1.1.1 Plasmas in the universe

1.1.2 How do plasmas affect us on earth?

1.1.3 Where does magnetic reconnection play into this whole shabang?

1.2 Magnetic Reconnection

1.2.1 The Generalized Ohm's Law

1.2.1.1 How do we derive this?

1.2.1.2 A breakdown of the terms

1.2.2 Regimes of Reconnection

1.2.2.1 Reconnection scaling parameters

i.e. why do we use S and L/d_i to characterize reconnection regimes?

Figure 1.1: Cartoon of places where reconnection can happen.

Figure 1.2: Diagram of reconnection regimes.

Figure 1.3: Diagram of Sweet-Parker reconnection.

1.2.2.2 Where do various systems line up?

1.2.2.3 What are we interested in?

1.2.3 Sweet-Parker Reconnection

1.2.3.1 A quick historical detour

1.2.3.2 What are the assumptions that go into Sweet-Parker?

1.2.3.3 Sweet-Parker Reconnection Rate Derivation

1.2.3.4 Application to Real Systems

1.2.3.4.1 What are some example parameters where reconnection occurs?

1.2.3.4.2 What time scales does Sweet-Parker predict?

1.2.3.4.3 What did we miss?

1.2.4 Hall Reconnection

1.2.4.1 Why should the Hall term appear?

1.2.4.1.1 What is the relevant physics that sets when the hall term matters

1.2.4.1.2 In what kind of plasmas does the hall term appear and when does it not?

Figure 1.4: Diagram of 2d hall reconnection

Figure 1.5: Flux tube changing size during reconnection causing pressure anisotropy build up.

1.2.4.2 What does hall reconnection look like

1.2.4.3 What's missing?

1.2.5 Kinetic Reconnection

1.2.5.1 What makes kinetic reconnection “kinetic”?

1.2.5.1.1 What do collisions do?

1.2.5.1.1.1 How quickly do collisions damp out non-Maxwellian features?

1.2.5.1.2 What makes a system kinetic?

1.2.5.1.2.1 What parameters set this?

1.2.5.1.2.2 What should we do in the lab to get this?

1.2.5.2 Where does Pressure Anisotropy come from?

1.2.5.2.1 Movement of flux tube

1.2.5.2.2 Effect of background field

1.2.5.2.2.1 Too low of background field does...

1.2.5.2.2.2 Too high of field does...

Figure 1.6: Simulated kinetic reconnection with changing guide field.

Figure 1.7: Diagram from Ohia of with and without pressure anisotropy in simulation.

Figure 1.8: Some figure from Jan's papers showing effects of pressure anisotropy

1.2.5.2.2.3 Goldilocks!

1.2.5.3 How does pressure anisotropy change what the reconnection looks like

1.2.5.3.1 Thinner reconnection layer? Use results from Jan's more recent papers.

1.2.5.3.2 Marginal Firehose Condition

1.2.5.3.3 Concluding: what features should we look for in the data?

1.2.5.4 Why do we want to measure it?

At the end of experimental setup I'll talk about why we want to do it in the lab but I think motivating why we care about kinetic reconnection as a process would be good here.

1.2.5.4.1 Simulation result overview

1.2.5.4.2 Spacecraft result overview

1.2.5.4.3 Experimental result?

1.3 Experimental Setup

1.3.1 Overall how does our experiment progress

Figure 1.9: Timeline of experimental sequence.

1.3.7.3 Laser based

2 PRESSURE WAVE

2.1 Introduction

Once I get Jan's rewrite of the intro + conclusion I can figure out what might go here.

Figure 2.1: dBz/dt plots for different Helmholtz fields

Figure 2.2: Greess et al. 2022 paper showing simulations with pressure wave.

2.2 Observations that lead us to look at this wave

2.2.1 Speed probe measurements

2.2.1.1 Flux expansion before shock layer

2.2.1.2 Wavefront that depends on configuration

2.2.2 Simulations

2.2.2.1 Different n and drive change feature

2.2.2.2 Change reconnection layer post reflection

2.3 Physical understanding of wave

2.3.1 Initial plasma configuration

2.3.2 Release in magnetic pressure

2.3.2.1 What would happen if plasma was immobile (replaced with perfect conductor)

All field is shielded at edge and there is no change in magnetic pressure in the bulk.

2.3.3 Wavefront tells plasma about pressure Release

2.3.3.1 Analogous system

Sound wave.

How does a sound wave propagate in a plasma? Fast magnetosonic wave!

Figure 2.3: Simple diagram of sound wave in container

2.3.4 Modeling magnetic field response

2.3.4.1 How do we create this model

2.3.4.2 Pressure wave is like a shield

2.3.4.3 Example

2.3.4.4 Why have we mentioned this?

2.3.4.4.1 Important for probe calibrations

2.3.4.4.2 Good for predicting effects of different coil configurations

2.4 Wave Simulation

2.4.1 Approximations

2.4.2 Linearizing MHD

2.4.3 Plasma Equilibrium + Symmetries

2.4.3.1 Types of Equilibrium

2.4.3.1.1 theta-pinch

2.4.3.1.2 screw-pinch

2.4.3.2 Types of Symmetries

2.4.3.2.1 z-symmetry

2.4.3.2.2 toroidal-symmetry

Table 2.1: Parameters for normalization

2.4.4 Simplified 1D equation

2.4.4.1 What does this look like?

A wave equation!

2.4.4.2 Normalizations

2.4.4.3 Normalized equation

2.4.5 Boundary conditions

2.4.5.1 $r = 0$ Boundary

2.4.5.1.1 $v = 0$ option

2.4.5.1.2 $\xi = 0$ option

2.4.5.1.3 What do we choose?

2.4.5.2 $r = R$ Boundary

2.4.5.2.1 What is physically happening at high radius in the coils?

2.4.5.2.2 Loop voltage sets dB_z/dt

2.4.5.2.3 Assuming MHD so far so let's keep assuming!

2.4.5.2.4 Vloop signal shape

2.4.6 Initial conditions

2.4.6.1 What form can we expect plasma to take?

2.4.6.2 What form do we use for these results

2.4.7 What does our simulation show?

2.4.7.1 There is a wavefront traveling inwards at fast magnetosonic

2.4.7.1.1 Low beta approximation giving Alfven

2.4.7.2 Once wavefront passes, plasma moves out

2.4.7.3 Converting to $\mathbf{B} \cdot \mathbf{d}$

2.4.7.4 In $\mathbf{B} \cdot \mathbf{d}$ we see flux moving outwards

As expected from MHD assumption.

2.5 How do we apply it to real data?

2.5.1 Base requirements

2.5.1.1 Cylindrical symmetry

2.5.1.2 Releasing magnetic pressure at high radius

2.5.1.3 Measurements along a radial chord

2.5.1.4 Known initial field

2.5.2 Extracting the wave speed from the data

2.5.2.1 Wave tracking

2.5.2.1.1 Edge finding

Figure 2.4: Data vs. crude minimum density vs. empirical minimum density

Figure 2.5: Diagram of what the more complex model looks like.

2.5.2.1.2 Inertia

2.5.2.1.3 Monte-carlo

2.5.2.1.4 Centered finite difference

2.5.2.1.5 Mean + Standard Deviation of Speed

2.5.3 Getting the density

2.5.3.1 Using the alfven speed

2.5.4 Minimum measurable density

2.5.4.1 Assuming sample resolution

2.5.4.1.1 What does this assumption derive

2.5.4.1.2 How does it compare to the data

2.5.4.1.3 We need a better approximation

2.6.2.3.3 How to simulate evolution approximately

2.6.2.3.4 Dispersion simulation results

2.7 Applications

2.7.1 Other machines where this is applicable

LAPD & MRX

Figure 2.13: Initial density for varying Helmholtz

Figure 2.14: Diagram of flux mechanisms.

Figure 2.15: Example diffusion simulation

Figure 2.16: Example of cross-correlation

2.7.2 Diagnosing gun failures

2.7.3 Measuring effect of different gun number and Helmholtz strength

2.7.3.1 Gun number

2.7.3.2 Helmholtz

2.7.4 Measuring diffusion coefficient

2.7.4.1 Diffusion theoretical model

2.7.4.2 Diffusion simulations

2.7.4.3 Applications of pressure wave model

I think I need to do a bit more research here to show that we can actually extract a diffusion coefficient.

Figure 2.17: Example of DTW

2.8 Future Research

2.8.1 Better wave tracking

2.8.1.1 Cross-correlation

2.8.1.2 Dynamic Time Warping

2.8.1.3 Using a model of what the wave looks like

2.8.2 Using fast-magnetosonic speed instead of alfven

2.8.2.1 Will this iteratively converge?

3 MULTI-TIP LANGMUIR PROBE

3.1 What's a Langmuir probe

Hershkowitz: Hershkowitz (1989) Hutchinson: Hutchinson (2002) Olson: Olson (2020)

Plasma diagnostics make a broad phylogenetic tree ranging from the variety of plasma parameters they can measure to their size and complexity. In the Big Red Ball we prefer simplicity and cheapness to some of the wilder diagnostic varieties so a common probe that we use is a Langmuir probe.

3.1.1 Basic Construction

These Langmuir probes are quite basic in construction. At it's simplest, a conductor is placed in contact with the plasma and a voltage is applied relative to ground which we will call the probe voltage, V_{probe} . This will locally perturb the plasma and collect a current, I_{probe} , which can be seen in figure 3.1. If $V_{\text{probe}} < V_{\text{plasma}}$, an electric field is formed that repels electrons and attracts ions and the inverse for $V_{\text{probe}} > V_{\text{plasma}}$.

Figure 3.1: A circuit for a very simple Langmuir probe. The probe is biased to the probe voltage, V_{probe} , relative to ground by the power supply. The conductor (white circle) collects ions and electrons from the plasma (pink circle) causing a current to the probe, I_{probe} .

Langmuir probes have been developed to work in a very wide range of plasma parameter configurations that well encompass the plasma parameters TREX achieves (see table 1.2).

3.1.2 Extracting Plasma Parameters

The most challenging part of these probes is the conversion of measured current to plasma parameters. Since we are trying to get a local measurement of the plasma parameters and we are also perturbing the plasma locally by touching it with a probe, we need to create a theory that correctly takes into account that perturbation such that we can get the plasma parameters. This often consists of a fitting procedure where the difference between the theoretical and experimental I-V curves is minimized.

Additionally, many a probe theory is purpose built for plasmas with no magnetic field. As we are studying magnetic reconnection in which there are in fact magnetic fields, this could change the I-V characteristic in unexpected ways. We'll discuss below why these effects are not very impactful and in future sections describe the theories we use for extracting the plasma parameters.

3.1.3 Plasma Perturbation

A problem often found in highly magnetized plasma devices is the long range perturbation to the plasma by the probe. In the Big Red Ball there are times where we have a relatively strong field and times when we don't so let's examine both cases.

3.1.3.1 Unmagnetized Perturbation

Let's examine this from an unmagnetized starting point. In this configuration, the probe collects nearly isotropically to an extent limited by the Debye length which creates a sheath around the probe and operates to

shield the electric field caused by the difference between V_{probe} and V_{plasma} . This length scale is very short and plasma can easily refill the sheath in this unmagnetized system.

3.1.3.2 Magnetic Field Effects

Now in a highly magnetized system (gyroradius far smaller than probe length scale) the plasma interacting with the probe comes from a flux tube approximately the size of the probe area projected into the magnetic field direction. Because of this, the probe can start “emptying out” the flux tube because of the difficulty of plasma to diffuse across field lines into the flux tube. This means the extend of the probe perturbation is far longer.

3.1.3.3 Perturbations in our System

We are quite lucky in that our system geometry reduces the impacts of flux tube emptying and the plasmas we are studying are often relatively unmagnetized.

3.1.3.3.1 Geometric Considerations The TREX experiment is (often) cylindrically symmetric and our probes are placed in different toroidal planes (see figure 2.6 for coordinate system reference). This means that without any toroidal field, any emptying only occurs in the plane of the probe which may still affect the probe I-V characteristic but is not affecting other probes measurements in a significant manner. When we do have a toroidal field, we also often have non-uniform B_r and B_z which means the flux tube passes through many different plasma parameters. This may help to average out any flux tube emptying because at different points along the flux tube more plasma may be able to enter the tube than just what is expected at the probe causing a reduced perturbation length.

Table 3.1: Langmuir probe characteristic scales.

3.1.3.3.2 Magnetic Field Considerations As we have magnetic fields in our system, we do need to worry about these flux tube effects. Fortunately, our magnetic field are relatively small and in the region we are often most interested in (where reconnection is occurring) the magnetic field is far smaller than the initial background field. We characterize this smallness by the ratio of the gyroradius to the radius of the probe area which is on the order of ???.

3.2 Hardware

There has been a long and storied history of probe building on the Big Red Ball especially for the development of multi-tip Langmuir probes. For some more information about our probes, see Olson (2020).

3.2.1 Physical Constraints

Our Langmuir probes need to satisfy a number of requirements.

- **Length:** The probe is attached to a port on the surface of the machine. This means it starts at a spherical radius of 1.5 m and must be inserted from there. Thus the insertable length should be fairly long and must be stable. This is described in 3.2.2.
- **Material:** We want our probe to survive the plasma exposure and not affect our vacuum pressure via offgassing. We also don't want to have to worry about secondary electron emission. We discuss this in 3.2.3.

Figure 3.2: Three stage probe shaft with an outer and inner garage and the main stainless steel shaft that connects to the probe.

- Probe Size:** We want to measure the plasma locally so our probe body needs to be small relative to the plasma gradients. It also needs to be able to fit through ball joints that can be mounted to the machine that have a radius of ???. These considerations are taken into account in 3.2.3.

3.2.2 Shaft Components

For our probe to reach everywhere we want and also actually be in the position we desire we need a long shaft with a sufficient amount of support to be accurate to a few centimeters. Why a few centimeters? Our plasma dynamics are reproducible but not to such an extreme that a centimeter is noticeably different. Also it's difficult with the probe length to achieve too much better.

3.2.2.1 Garages

As can be seen in figure 3.2, the probe shaft is a multistage system. Each stage consists of some tubing where connections between different stages are made using quick-connect high-vacuum fittings (like part 3486N32 from McMaster-Carr).

We mount the probe to the machine using a flange on the outer garage or a ball joint (as seen in the figure). Then we can move each garage

independently to insert the probe a desired length.

3.2.2.2 Shaft materials

We need to sufficiently support our probe and the shafts themselves so we use stainless steel until we enter the plasma region in which we change to alumina.

For the shafts, stainless steel is vacuum safe, tolerant to plasma interaction, and can support the weight of the structure easily without excessive flexing. Unfortunately, as a conductor, it will act as a long Langmuir probe that will create a ray in the machine at a single potential. This will perturb the plasma much more significantly than using an insulator.

To that end we use alumina, a high temperature ceramic whose surface will accumulate charge such that it'll be left at the floating potential (the potential at which the ion and electron currents balance). This helps to perturb the plasma less as there is no net current to the shaft and thus the plasma should (hopefully) be less perturbed.

Right near the end of the probe shaft, we use stainless steel tubing to connect from the alumina to the probe body. This is to reduce the overall size of the shaft in perturbing the plasma at the probe and is only for 10 cm of length.

3.2.2.3 Centering Collet

Each shaft/garage, is held in place by the sliding vacuum seal that connects it to its larger garage. Unfortunately this gives only a single point of contact for making the shafts concentric. This would cause excessive drooping of the probe and may be so bad as to cause the probe to hit the edge of the machine when being inserted/removed.

To fix this issue, we have used centering collets that allow the inner shaft/garage to move while being held in place by the outer garage. These

Figure 3.3: Picture of the end of the multi-tip Langmuir probe. Image from Gradney (2025).

can be both machined or 3D printed. When 3D printed we can make these to also hold the o-rings so they are double-acting.

3.2.2.4 Feed-thru

We need some way to extract the signals from the probe tip. Because of the construction of our probe and for simplicity purposes, the probe shaft is at vacuum pressure. Thus we attach a feed-thru to the end of the can from figure 3.2. This is constructed using two DB-25 hermetically sealed connectors where we solder the wires directly to the vacuum side of the can and then can easily move and connect the probe externally.

3.2.3 Tip Components

3.2.3.1 Probe body

Our probe does not need to withstand extreme heat fluxes and our vacuum conditions don't need to be perfect so we are lucky enough to be able to use a 3D printed probe body.

Figure 3.4: Probe body from engineering sketch. Created by Joe Olson.

This is constructed using stereolithography which gives a sufficient resolution for the probe. Additionally the plastic used holds up well in vacuum. The body must connect to two different diameter stainless steel tubes (as can be seen in figure 3.3). Thus we use two annuli whose inner/outer radii match the tubing.

The tubing exists to connect the probe to the main shaft holding it up and also a small B-dot coil which is discussed in 3.2.4.

3.2.3.2 Tip material + size

To collect current, we use 16 separate tips which each sample a point on the IV curve. We make these tips out of Molybdenum which requires us

to connect the tips to the signal wire using a friction fit.

3.2.3.2.1 Why use Mo Even though Molybdenum has its difficulties with connections, it has a high work function which helps to reduce secondary electron emission which can change the shape of the IV-characteristic.

3.2.3.2.2 Size considerations We expect the current to the tips to be on the order of 1 kA/m^2 . We measure the current across a 'sense' resistor (as discussed thoroughly in 3.3.2) but we don't want to have to use high power resistors for this. Thus we choose our current to be on the order of 10 mA which is feasible by having a tip area on the order of 10 mm^2 . This amount of current also gives a reasonable signal-to-noise ratio.

Unfortunately, the probe is not all that cylindrical which means that the idealized probe theories we use are not as precise as we may have hoped. Future probe designs could use longer and smaller diameter tips to avoid this issue.

3.2.3.3 Tip Shielding

We protect each tip from the base of the probe body using PTFE/teflon. Teflon isn't great in a vacuum environment because of offgassing but does the trick and is cheap and easy to use. After inserting the tip into the probe body we push the teflon on and apply a small amount of vacuum-safe epoxy at the base to hold the shielding in place.

3.2.3.3.1 Why shield at all? We could potentially shorten each tip so the collecting area extends all the way to the probe body. Unfortunately because of the increased size of the body this can cause shadowing effects where tips on one side of the probe have a different IV-characteristic than those on the other. This 'shadowing' is caused by plasma flow parallel to the tip direction which gets intercepted by the probe body.

Figure 3.5: Simplified cartoon of the expected mach effect for the multitip probe. Left panel inspired by Merlino and D’Angelo (1987), Fig. 10.

3.2.3.3.2 First order mach effects to avoid Another reason to shield the probe is to avoid mach effects that would cause different IV-characteristics for tips on opposite sides. As can be seen in figure 3.5, in an ideal mach probe the ions are prevented from easily accessing the “shadowed” side of the probe (right side) because of their inertia. If we shrink the probe body and increase the distance the tip is from the probe the mach effect is reduced because ion inertia is not sufficient to prevent collection. This is only approximate though and we sometimes do see effects that could be caused by shadowing. For an in depth discussion of mach probes we refer the interested reader to Chung (2012).

3.2.4 B-dot Coils

Since we don’t know the exact location of the probe and the plasma is not perfectly reproducible, it’s especially useful to have measurements we can compare to other diagnostics to locate the probe in space and around the reconnection region. To do this we use hand wound three axis Bdot coils that can measure the change in magnetic field near the tips.

3.6 Results

What is the benefit of doing all this work?

Figure 3.17: Plot of isat currents from BRL

Figure 3.18: Radial chord of initial density with Hutchinson vs BRL.

Figure 3.19: Comparison of expected E from Ohm's law and measured E.

3.6.1 Measurement of low densities

3.6.1.1 How does Hutchinson vs BRL treat ion saturation

3.6.1.2 What are the experimental predictions that Hutchinson vs BRL have

3.6.1.3 How does that change the results

3.6.2 Noise resilience

Not sure how best I should show this.

3.6.3 Fits more accurate

- Each fit uses many data points
 - Don't have to arbitrarily cutoff data points

3.6.4 Extracting electric fields

3.6.4.1 Where do we expect electric fields to be

3.6.4.2 Do we see them there

4 PRESSURE ANISOTROPY PROBE

4.1 How can we measure Pressure Anisotropy

4.1.1 Thomson Scattering

4.1.1.1 Pros

4.1.1.2 Cons

- Requires a lot of playing around with optics
- Size of machine
- Don't have much in-lab expertise
- Getting all the photons is tough
- Don't have optics stuff setup

4.1.2 Directional Langmuir Probe

4.1.2.1 Pros

- Simplicity
- Cost
- Mobility

4.1.2.2 Cons

- Difficult to interpret results precisely (luckily only need relative stuff)
- Can't perfectly model
- Requires a lot of playing around with circuits

4.4.2.3.2 Error bars

4.4.2.3.2.1 Monte-carlo

4.4.2.3.2.2 Other options

4.4.2.3.2.3 Why can we ignore non-bi-maxwellian features

4.5 Curve Fitting

We will use ODR like mentioned in Te section.

Figure 4.17: Comparison of alignment using $B_z = 0$ or $\mathbf{b} \cdot \mathbf{d}$ cross correlation

4.5.1 Combining multiple shots

4.5.1.1 Timing alignment

4.5.1.1.1 $B_z = 0$ alignment

4.5.1.1.1.1 Aligns where we expect Anisotropy

4.5.1.1.1.2 Depends heavily on prior $\mathbf{b} \cdot \mathbf{d}$ data

4.5.1.1.2 $\mathbf{b} \cdot \mathbf{d}$ cross correlation

4.5.1.1.2.1 Still requires smoothing to get rid of initial oscillation impact

4.5.1.1.3 Result comparison

4.5.1.2 Averaging of core data

4.5.1.2.1 Weighted average of relay on/off

4.5.2 Fitting shell

4.5.2.1 Use all shell data

4.5.2.2 Fit using BRL

4.5.2.3 Fits pretty good

4.5.3 Fitting core

4.5.3.1 Fitting using full routine

4.5.3.1.1 Slow

4.5.3.1.2 Model not perfectly representative

4.5.3.2 Fitting tips independently

4.5.3.2.1 Individual fitting method

4.5.3.2.2 Holding Vprobe constant

4.5.3.2.3 Exponential fitting method

4.5.3.2.4 Spherical harmonics

4.6 Results

Figure out what my results are once I have some reasonable results

4.6.1 Drive cylinder

4.6.1.1 What did we try

4.6.1.2 Why didn't we see pressure anisotropy

4.6.1.2.1 In the bdot data

4.6.1.2.2 In the PA data

4.6.2 3 coil

4.6.2.1 How much anisotropy should we expect

4.6.2.2 What setups did we try

4.6.2.3 Old results of just comparing radar plots

4.6.2.4 New results using independent fitting

5 CONCLUSION

5.1 Summary of thesis

- 5.1.1 Using pressure waves to measure density
- 5.1.2 Upgrading langmuir probe analysis and new possibilities
- 5.1.3 Using directional langmuir probes for measuring pressure anisotropy

5.2 Future work

- 5.2.1 Pressure wave
 - 5.2.1.1 Aforementioned future work
 - 5.2.1.2 Extracting cross-field diffusion
- 5.2.2 Langmuir Probe
 - 5.2.2.1 Prepared to analyze lots of cool data
 - 5.2.2.2 Extract out electric field
- 5.2.3 PA Probe
 - 5.2.3.1 Try more configurations
 - 5.2.3.2 Map out full pressure anisotropy during shot
